

## **“The Importance of Endogenic Processes in Shaping Earth and Sustaining Life”**

It is often said that Endogenic processes in geology are a function of a body's internal geodynamic activity. They comprise volcanic, tectonic, and isostatic processes, which shaped the surfaces of all terrestrial planets, the Moon, and basically all other Solar System bodies with solid surfaces that have been observed in some detail. Many people claim that Endogenic processes are driven by the internal heat of the Earth, which in turn results from the radioactive decay of elements deep beneath the surface. This heat bubbles upward providing a huge driving force that bends, lifts, and moves Earth's rigid outer layer.

Another factor to consider is gravitational differentiation has led to the stratification of the earth into geospheres of varying density. Endogenic processes have been responsible for shaping the earth's relief and the formation of many of the most important mineral resources.

According to experts' Gravitational differentiation has led to the stratification of the earth into geospheres of varying density. On the surface it is also manifested in the form of tectonic movements, which, in turn, lead to the tectonic deformation of crustal and upper mantle rocks. The accumulation and subsequent discharge of tectonic stresses along active faults causes earthquakes.
