Conformational Changes during Potassium-Channel Gating Jakob Renhorn, 2018-04-09 Voltage gated ion channels have a paramount importance in many physiological processes such as cell to cell communication action potential propagation and cell motility Voltage gated ion channels are characterized by their ability to sense membrane voltage and to greatly change channel activity in response to small changes in the voltage The ability to sense voltage resides in the four voltage sensor domains VSDs surrounding the central ion conducting pore Membrane depolarization causes the inside of the membrane to become positively charged electrostatically repelling the positively charged fourth transmembrane segment S4 or voltage sensor in the VSD causing the voltage sensor to move outwards This motion provides necessary energy to open the pore and allow ion conductivity Prolonged channel activation leads to alterations in the selectivity filter which cease ion conductivity in a process called slow inactivation In this thesis we investigated the movement of S4 during activation of the channel We also studied the communication between the four subunits during activation as well as the communication between the pore domain and VSD during slow inactivation We have shown that voltage sensors move approximately 12 Å outwards during activation The positively charged amino acid residues in S4 create temporary salt bridges with negative counter charges in the other segments of the VSD as it moves through a

membrane We have also shown that the movement of one of the four voltage sensors can affect the movement of the neighboring voltage sensors When at least one voltage sensor has moved to an up position it stabilizes other voltage sensors in the up position increasing the energy required for the voltage sensor to return to the down position We have also shown reciprocal communication between the pore domain and the VSDs Alterations in the VSD or the interface between the pore and the VSD cause changes in the rate of slow inactivation Likewise modifications in the pore domain cause changes to the voltage sensor movement This indicates communication between the pore and the VSD during slow inactivation The information from our work could be used to find new approaches when designing channel modifying drugs for the treatment of diseases caused by increased neuronal excitability such as chronic pain and epilepsy
